

Flutter Slider Demo, a simple widget that demonstrates how Flutter creates interactive user interfaces using a slider.

The code starts in the **main()** function, where **runApp()** launches the widget. I then created a **MaterialApp**, which sets the title, theme, and displays the home page.

Next, I used a **StatefulWidget** because the slider value changes while the widget is running. Unlike a **StatelessWidget**, a **StatefulWidget** allows the interface to update whenever the data changes.

Inside the home page, I designed the interface using a **Scaffold**, which provides the app bar and the main layout. The content is placed inside a **Card** with padding to keep the design clean and organized.

The main feature is the **Slider** widget. It allows the user to adjust the music volume between **20% and 100%**. Whenever the slider is moved, the **onChanged** callback is triggered. Inside this callback, **setState()** updates the **_volume** variable, and Flutter automatically rebuilds the widget to display the new value.

Below the slider, a text widget displays the current volume as a percentage, giving the user immediate visual feedback.

Overall, this project demonstrates how Flutter widgets can be used to create responsive, interactive, and cross-platform user interfaces with simple state management.
